

README

1. Because this app uses php, it is necessary to download PHP7 on the platform you are using and save the directory path as one of your environmental local variables. For Windows, you want to add the directory in the PATH environment variable.
2. Download XAMPP. Once it is download, go to the Control Panel and make sure Apache is running. If it is unable to be configured, make sure Apache is downloaded before proceeding.
3. Once XAMPP is downloaded, open the folder and locate the htdocs folder. Place the project submission within the folder.
4. Run the application using localhost in order to parse through the php files and receive data from all of the queries.
